Question 28) GetMapping:

Here's why each of the other choices doesn't apply based on the provided annotation `@GetMapping("/student/ids")`:

A. It accepts a student ID as a parameter. - This statement is likely incorrect because the path `"/student/ids"` suggests that the method could be intended to retrieve multiple student IDs or handle a collection of IDs, rather than a single ID. However, without more context or the method signature, we cannot definitively say that it accepts a student ID as a parameter.

B. It returns a student ID. - This assumption is also likely incorrect. The path `"/student/ids"` implies that the method might return a collection of student IDs (e.g., a list of IDs). The method could return any type of response related to student IDs, not necessarily a single ID.

C. The method will not be called because the mapping is malformed. - There is no indication from the annotation itself that the mapping is malformed. The path `"/student/ids"` is a valid mapping for a URL and would correctly map HTTP GET requests to the method it annotates.
